Level-vector resolution and classification performance: cannibalism_vs_fc

Primary summary-level analysis; N = 1000 unique randomly sampled level vectors

A. Total skeletal detail and performance - cannibalism_vs_fc

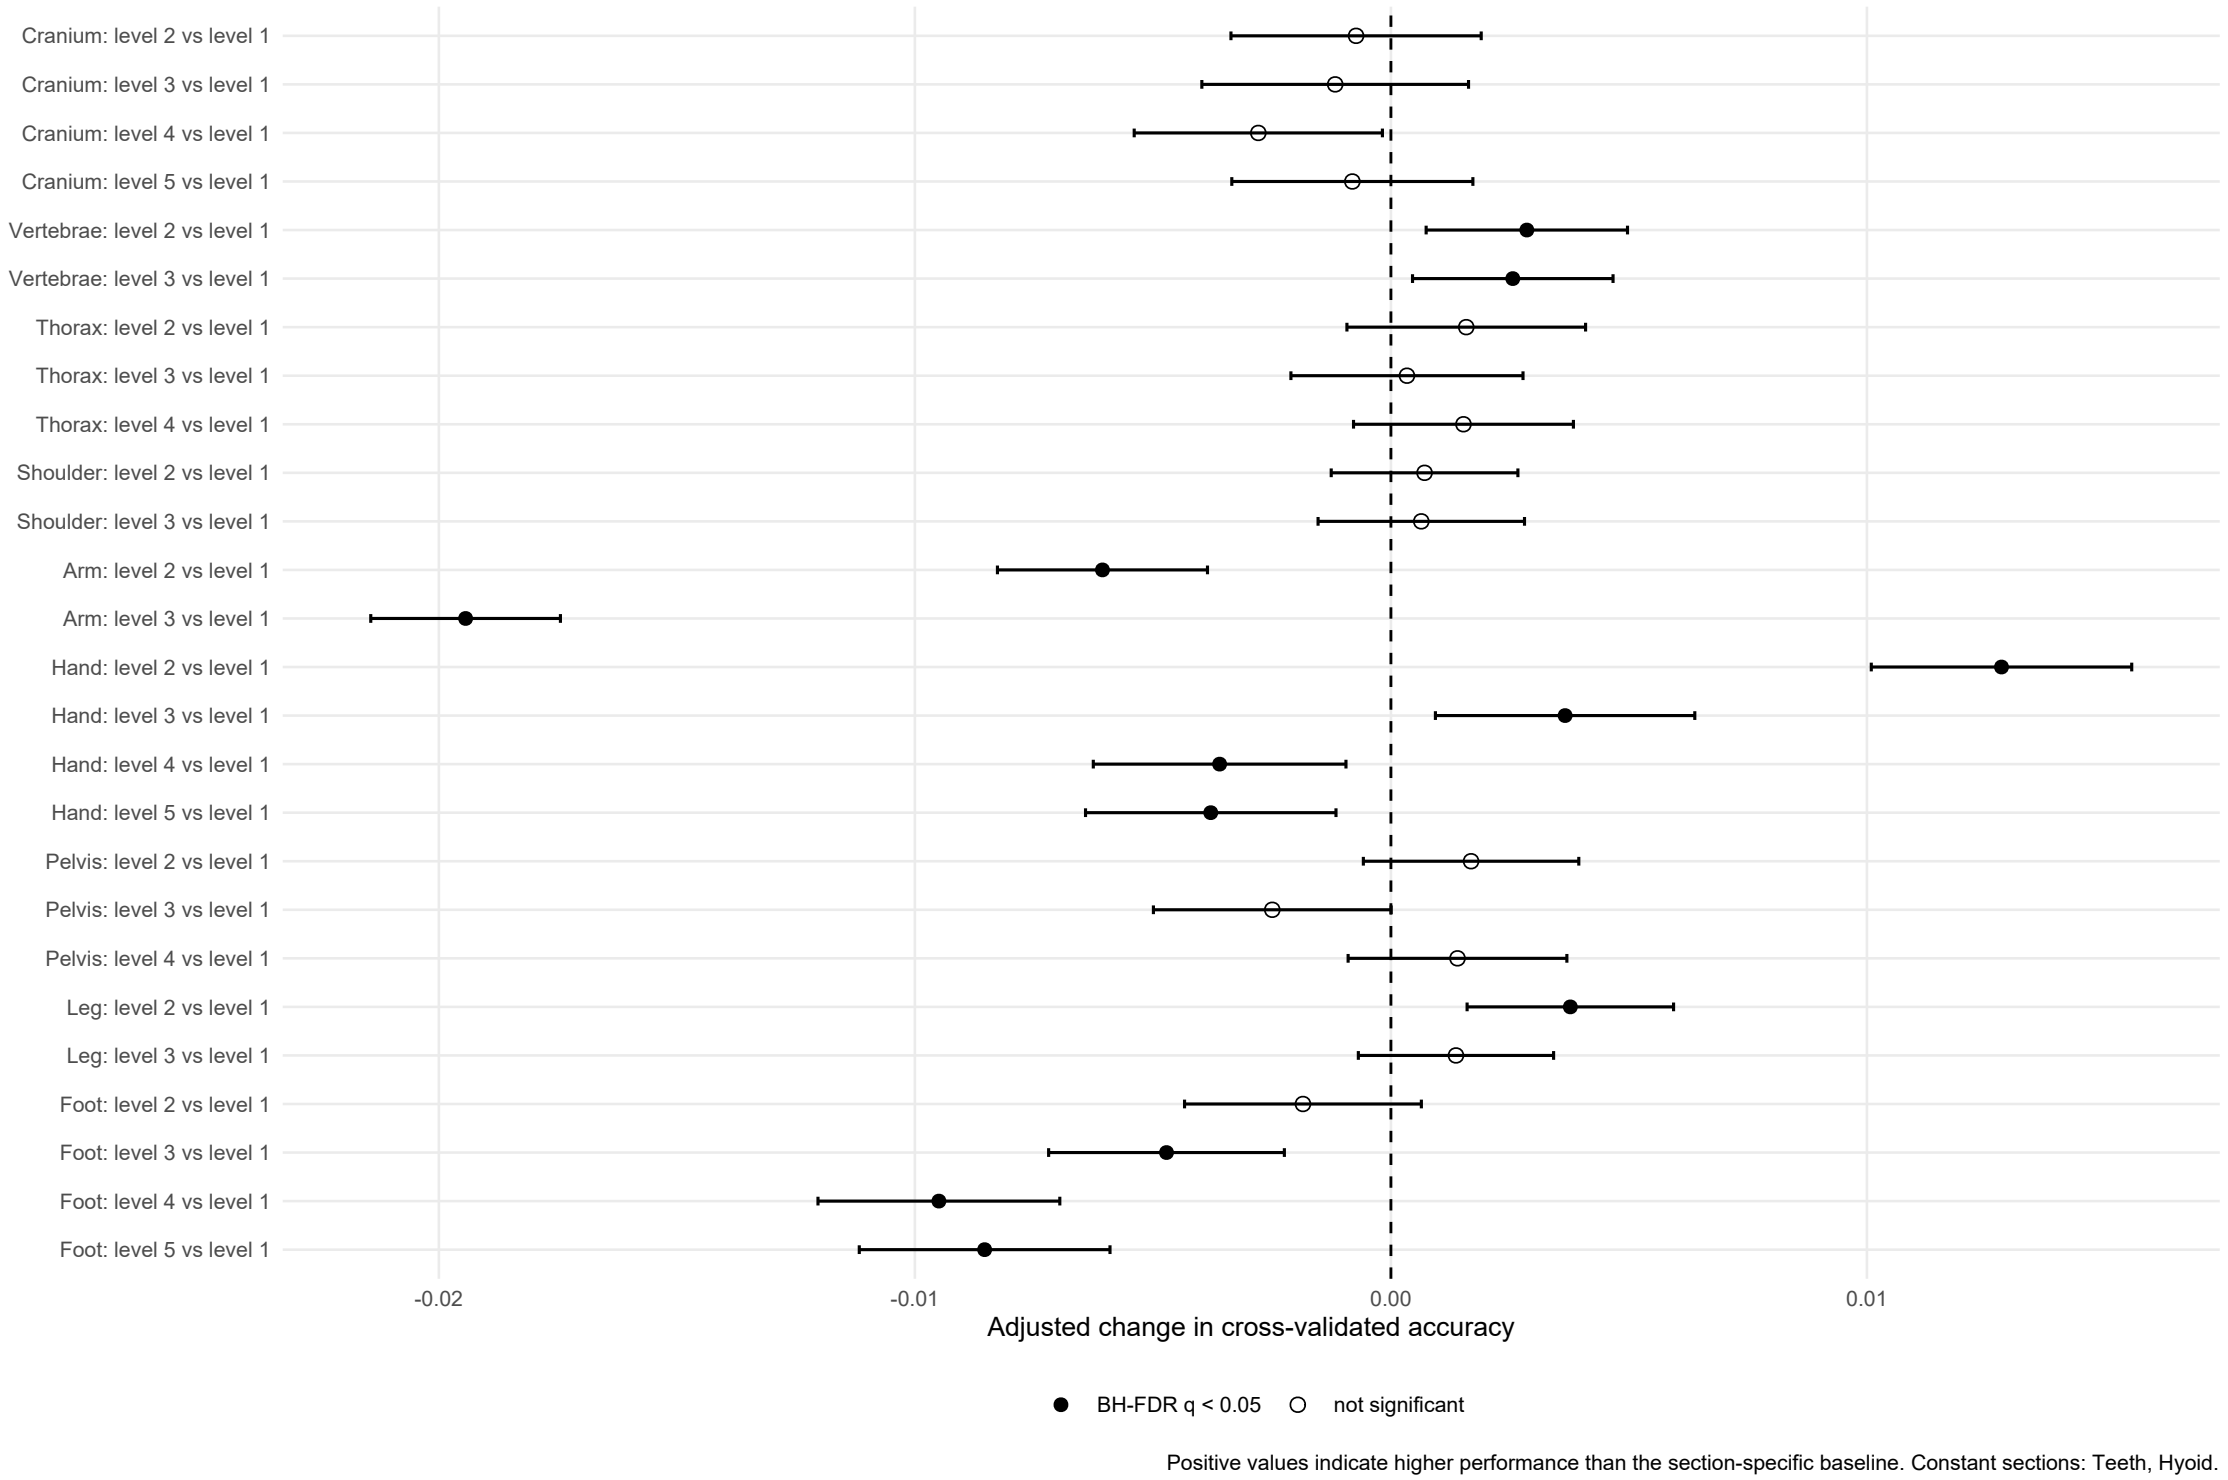

N = 1000 unique vectors; HC3 slope = -0.0014 per level (95% CI -0.0017 to -0.0011); adjusted R^2 = 0.072; Spearman rho = -0.306; GAM deviance expla

Exactly 1000 points are drawn. Horizontal jitter only; solid line = linear model with 95% CI; dashed line = GAM nonlinear check.

B. Mutually adjusted section-level effects

Difference from each section's lowest level, adjusted for all other varying sections; HC3 95% CIs; BH correction across 26 contrasts

Positive values indicate higher performance than the section-specific baseline. Constant sections: Teeth, Hyoid.
